USE CASES

The cases that don't fit a rule table.

VATmiraal is built for the determinations where the answer follows from a combination of conditions, not from a single lookup. That is exactly where simple tools quietly make the wrong call. A few examples:

The 629 trap.

An exempt party with no right to deduct files a 629, never a periodic return, so the intra-Community acquisitions and the reverse charge on purchased services it owes surface nowhere in the ordinary return. Checking status against each entry brings those obligations to the surface and separates them from acquisitions that stay under the threshold or fall under an elected scheme.

ABC and chain transactions.

Ascribing the single transport to one leg fixes everything downstream: which supply is the exempt intra-Community leg, who has to register, whether the triangulation simplification holds. It becomes a puzzle once an order comes in and the goods for it may be drawn from two different countries: which country supplies which part determines which leg crosses the border, and with it the VAT treatment of the whole chain.

Petrochemicals: one flow, several rates.

A volume of liquid in a tank is split in fixed proportions across three processes and emerges as products that each carry their own sales rate. The VAT has to follow that split: the right rate for each fraction leaving the process. VATmiraal models the process, so the allocation is correct and traceable, even when the proportions or the rates change.

Mixed and partial deduction.

A general pro-rata ratio or the actual-use method, carried per party and applied per line, with capital-goods revision tracking the five- or fifteen-year window long after the original entry. The deductible share is exact; what breaks is holding it consistent by hand across every line and every revision year.

Reverse charge, correctly attributed.

Several reverse-charge rules can fire on a single entry: a non-established supplier, work on immovable property, an intra-Community service. Which one designates the debtor depends on the filing status of the declarant and the establishment of the supplier, and each routes to a different box in the return. The answer is the combination, not the first rule that fits.

Plan the treatment before you commit.

Run the determination forward over assumed facts instead of backward from a posting. Vary the establishment, who arranges transport, the counterparty's status, and read off how the debtor, the place of supply and the return shift with it. Structuring, tested against the encoded law, before anything is booked.

See it run these on your own data.
